Report

Team Members (1): Jake Huey

Initial Decisions: Python, VS code

Data structures: Arrays and Dictionaries

Reasoning: easy to work with. We used a dictionary to store all the information where the key was a string and the value was the value associated with that string.

For example, Key: StLastName and value: 'COOKUS'

Task Log (just me):

- Parsing the file and storing it in my "database" (~20-30mins)
- Search functions (~5 hours+)
- main/run (~30mins-1 hour)

Notes:

- Parsing the file took a little bit of time because we were debating whether to write to a file and then extract from there or use a CSV file reader due to the nature of the formatted data.
- The search functions took a long time because every task was specific and we needed to clarify my output. I got a lot of bugs here because I wanted my program to handle different invalid inputs
- Bugs found:
 - Differentiating between Grade Number High and Grade Number. I was stuck on this for ~30 minutes and then I realized that my search_grade function was just checking 'H' and not 'High'
 - Same issue but with Student LastName and Student LastName Bus

Final Notes:

- Great designed lab to get into the thinking habits of databases!
